Notations of Multi-Linear Algebra

Definition

Tensor products of a vector space V are multi-linear maps, meaning that if we multiply any of the elements $V_1 \otimes V_2 \otimes \dots \otimes V_r \rightarrow \mathbb{R}$ by a scalar, the result $V_1^* \otimes V_2^* \otimes \dots \otimes V_r^*$ (i.e the tensor product) will also be multiplied by the same scalar.

Definition

A (r,s) tensor field in V is given by the set of elements of the tensor products where V_s^r r times of $V \otimes \dots \otimes V$ multiplied by s times of $V^* \otimes \dots \otimes V^*$.

Riemannian Manifolds

A Riemannian manifold (M,g) is a form of smooth manifold which admits a Riemannian metric.

Definition

A Riemannian metric is a $(0,2)$ tensor field $g \in T^2(M)$ such that for all $p \in M$, g_p is a bilinear, symmetric and positive definite ($g_p(v, v) > 0$ for every $v \neq 0, v \in T_pM$) inner product on T_pM .

Every smooth manifold admits at least one Riemannian metric.

Levi Civita Connection

Definition

A connection is a map on the vector bundle $\pi: E \rightarrow M$ where

$$\nabla: \mathfrak{X} \times \Gamma(E) \rightarrow \Gamma(E)$$

. $\nabla_v T$ is defined as the connection on M for all $v \in \mathfrak{X}(M)$ and $S, T \in \Gamma(E)$. An affine connection is essentially a map between two neighbouring points in a tangent space.

Definition

The Levi-Civita Connection is a unique, symmetric and torsion free connection that can be induced on any manifold (M, g) which satisfies the following conditions:

- 1 $dg(X, Y) = g(DX, Y) + g(X, DY)$
- 2 $\nabla_X Y - \nabla_Y X = [X, Y]$

Completeness

- 1 If and only if its metric space is complete (Hopf-Rinow)
- 2 Its exponential map \exp_p can be defined on the entire TM for all $p \in M$ and therefore γ can be extended between $(-\infty, \infty)$
- 3 Any two points, say p, q , can be connected by a length minimising geodesic whose distance $d(p,q)$ is the minimum length of all possible curves in the direction p to q .
- 4 All bounded closed subset in M are compact.

Riemannian Distance

The Riemannian distance is the shortest length (also called a geodesic) of a curve between two points on a Riemannian manifold.

Definition

We can define the Riemannian distance between two points p, q by setting a piecewise smooth curve $\gamma: [a, b] \rightarrow M$ with the tangent vector $T_{\gamma t}M$ given by $\dot{\gamma}(t) = d\gamma \frac{d}{dt}$ for all $t \in [a, b]$. The length of the curve, $L(\gamma)$, can be written as

$$L(\gamma) = \int_a^b \sqrt{\langle \dot{\gamma}(t), \dot{\gamma}(t) \rangle_{\gamma(t)}} dt$$

. If $L(\gamma) = d(p, q)$, we call the curve length minimising.

Sectional Curvature

Definition

For a point $p \in M$ and a 2-dimensional subspace or plane $\Pi \subset T_p M$, we define the sectional curvature of Π at p as

$$K(\Pi) = K(x, y) \quad (1)$$

$$: = \frac{R_m(x, y, y, x)}{g(x, x)g(y, y) - (g(x, y))^2} \quad (2)$$

where x, y are vectors $\in \Pi$ which form the basis and R_m denotes the Riemann curvature tensor.

Properties of the sectional curvature:

- 1 $K(x, y)$ is independent of the choice of $x, y \in \Pi$
- 2 If the vector basis $\{x, y\}$ is orthonormal, then $K(\Pi) = R_m(x, y, y, x)$

Ricci Curvature

Definition

The Ricci curvature tensor is defined by

$$\text{Ric}(X, Y) := \text{tr}(R(\cdot, X)Y)$$

. tr denotes a trace, which is simply a contraction map.

Properties of the Ricci curvature:

- 1 In local coordinates, the Ricci curvature tensor can be written as

$$\text{Ric} = \text{Ric}_{ij} dx^i \otimes dx^j$$

- 2 Since R is symmetrical (i.e. $\text{Ric}(X, Y) = \text{Ric}(Y, X)$ for all $X, Y \in \mathfrak{X}$), tracing through any of the two arguments returns a result of either Ric or 0.

Bonnet Myers Theorem

Theorem

The Bonnet Myers theorem states that for any complete Riemannian manifold (M^n, g) whose sectional curvature, $sec(M) > \delta$, where δ is a positive constant, its Ricci curvature, R , satisfies:

$$Ric(M) \geq \delta(n - 1)$$

. We can then estimate its diameter, $diam(M)$, since it is always bounded by

$$sup_{p,q \in M} dist(p, q) \leq \frac{\sqrt{\pi}}{\delta}$$

. This is sufficient to show that M is compact.

-Cheng later proved in his rigidity theorem that all manifolds which satisfy the Bonnet Myers theorem have a constant sectional curvature k .

Outline of the Proof

- Assume that there exists a R which satisfies $\text{dist}(p,q) \leq \frac{\sqrt{\pi}}{\delta}$
- We also assume that there exists a geodesic γ between points p,q that is defined on the interval $[0,L]$ such that $|\gamma'| = 1$ after re-parametrisation.
- set a parallel unit vector field to γ (i.e. $\langle W, \gamma' \rangle = 0$) and $V(t) = \sin\left(\frac{\pi t}{L}\right)$
- $L'_0 = 0$ since γ is a geodesic
- Using the second variation of arc length equation

$$-\int_0^L \langle V'' - R(V, \gamma')\gamma', V \rangle dt$$

We can prove that $L(x(s, \cdot)) = L_x(s) \leq L_x(0) = L(\gamma)$ if s is infinitesimally small. Therefore, we can show that length of the curve $x(s, \cdot)$ is actually shorter than γ between $p,q \Rightarrow$ contradicting!
