Chromatic Number Of The Plane

Chromatic Number Of The Plane

In 1950, Edward Nelson asked the following question:

In 1950, Edward Nelson asked the following question:

Open Question (The Hadwiger-Nelson Problem)

How many colors are needed to color the points of the plane such that no two points exactly 1 unit distance apart are assigned the same color?

In 1950, Edward Nelson asked the following question:

Open Question (The Hadwiger-Nelson Problem)

How many colors are needed to color the points of the plane such that no two points exactly 1 unit distance apart are assigned the same color?

This seemingly simple question gave rise to many more discoveries as it captured the attention of many prominent mathematicians such as Erdos. We will refer to this as the **chromatic number of the plane** henceforth.

In 1950, Edward Nelson asked the following question:

How many colors are needed to color the points of the plane such that no two points exactly 1 unit distance apart are assigned the same color?

This seemingly simple question gave rise to many more discoveries as it captured the attention of many prominent mathematicians such as Erdos. We will refer to this as the **chromatic number of the plane** henceforth.

Slightly Less Overwhelming Problem

The entire plane is an infinite set of points; how do we tackle this problem?

The entire plane is an infinite set of points; how do we tackle this problem?

Theorem (De Bruijn–Erdos's Compactness Theorem)

An infinite graph G is k-colorable if and only if every finite subgraph of G is k-colorable.

The entire plane is an infinite set of points; how do we tackle this problem?

Theorem (De Bruijn–Erdos's Compactness Theorem)

An infinite graph G is k-colorable if and only if every finite subgraph of G is k-colorable.

This theorem essentially reduces the problem down to finite graphs, which are much easier to analyze.

The entire plane is an infinite set of points; how do we tackle this problem?

(Not Coffee) Filters

(Not Coffee) Filters

One of the ways to tackle this problem is to use filters and ultrafilters, defined as follows:

One of the ways to tackle this problem is to use filters and ultrafilters, defined as follows:

Definition (Filter)

A filter on a set X is a collection \mathcal{F} of subsets of X(i.e. $\mathcal{F} \subseteq P(X)$) satisfying the following criteria:

- $X \in \mathcal{F} \text{ and } \emptyset \notin \mathcal{F}.$
- **2** If $Z \subseteq Y \subseteq X$ and $Z \in \mathcal{F}$, then $Y \in \mathcal{F}$.

3 If $Y, Z \in \mathcal{F}$, then $Y \cap Z \in \mathcal{F}$.

< ロト < 同ト < ヨト < ヨト

One of the ways to tackle this problem is to use filters and ultrafilters, defined as follows:

To prove De Bruijn-Erdos, we introduce one key concept:

To prove De Bruijn-Erdos, we introduce one key concept:

Definition (Axiom of Choice)

Every family ϕ of nonempty sets has a choice function, i.e., there exists a function f such that $f(S) \in S$ for every S from ϕ .

< □ > < □ > < □ > < □ > < □ > < □ >

To prove De Bruijn-Erdos, we introduce one key concept:

Definition (Axiom of Choice)

Every family ϕ of nonempty sets has a choice function, i.e., there exists a function f such that $f(S) \in S$ for every S from ϕ .

The idea is to take f in this case is the chromatic coloring function, thus we can show that since a finite graph is a subset of the infinite plane their chromatic numbers must be equivalent by the ultrafilters.

I may have lied. I apologize, but the lower bound isn't actually 4. We have Aubrey De Grey to blame for that. In fact, the lower bound is actually 5, as we will see in his novel construction.

De Grey's Construction

Definition (Monochromatic Triple)

A monochromatic triple is a set of 3 vertices that are colored the same color.

Definition (Linking Vertices)

Linking vertices are the vertices at distance 2 from the center.

Figure: A cell and its various colorings.

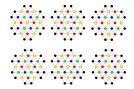

Figure: A honeycomb and its various colorings.

De Grey's Construction

Definition (Linking Diagonal)

A linking diagonal is a pair of linking vertices located in opposite directions from the center.

Definition (Specific Coloring)

A specific coloring is a coloring such that two opposite linking vertices are the same color as the center and all the other four are a second color.

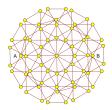

Figure: A hive.

The pictures of the large graphs are not shown due to visual impenetration. The idea is to start from a hexagonal cell and construct a swarm graph, which contains 52 copies of the cell that cannot have a monochromatic linking diagonal. This then allows us to perform the same operation on a moser wheel, which produces the solution.

Figure: A Moser Wheel.

I'm tired of this problem. Can I have another one?

The Hadwiger-Nelson problem has a rich history, which led to many further explorations. We will discuss two of them:

- Polychromatic Number of The Plane
- Chromatic Number of The *n*-dimensional Space

・ ロ ト ・ 同 ト ・ 三 ト ・ 三 ト

Extension (Polychromatic Number of The Plane)

What is the smallest number of colors needed for coloring the plane in such a way that no color realizes all distances?

Extension (Polychromatic Number of The Plane)

What is the smallest number of colors needed for coloring the plane in such a way that no color realizes all distances?

In other words, for any color *i*, it is assigned a distance d_i which is forbidden; no two vertices may be exactly d_i apart.

Extension (Polychromatic Number of The Plane)

What is the smallest number of colors needed for coloring the plane in such a way that no color realizes all distances?

In other words, for any color *i*, it is assigned a distance d_i which is forbidden; no two vertices may be exactly d_i apart.

We can in fact bound χ_p as we did for χ .

Theorem (Raiskii's Theorem)

$$\chi_{p} \ge 4$$

(日)

æ

We can in fact bound χ_p as we did for χ .

Theorem (Raiskii's Theorem)

$$\chi_{p} \geq 4$$

This bound is not as simple as the Moser Spindle construction, although the proof is quite nice.

3

Lower Bound

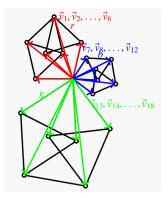

Figure: Merkov's Construction

The idea is to use a proof by contradiction on this specific construction. We count the number of arrangements of red, blue, and green vertices and show that it exceeds the total number of arrangements of vertices.

イロト 不得 ト イヨト イヨト

Upper Bound

Theorem (Classic Upper Bound) *We have that*

 $\chi_{\it P} \leq 6$

(日)

3

Upper Bound

Theorem (Classic Upper Bound) We have that

$$\chi_{p} \leq 6$$

3

Theorem (The Upper Bound)

```
\chi(\mathbb{E}^n) \leq \lfloor 2 + \sqrt{n} \rfloor^n.
```

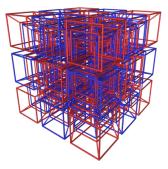

Figure: A Tesseractic tiling.

Method

Size the tesseracts such that their diagonals have lengths less than 1 and two neighboring tesseracts have their monochromatic points at least 1 apart.

July 17, 2023

Conclusion

The Hadwiger-Nelson Problem is a quite interesting and mind-boggling exploration. It has captivated the minds of mathematicians throughout the twenieth century and beyond. Perhaps you can make a difference; read my paper for more information.

Here are some questions to stimulate your thinking:

Extension (Three Dimensions)

Can you find better bounds for the n = 3 case of the n-dimensional chromatic number of the space?

Extension (Rational Coloring)

If we only consider rational points on the plane, do the bounds still remain inequalities or can we find explicit values? (Hint: $\mathbb{R} > \mathbb{Q}$.)
