

# Error-Correcting Codes Derived from Cellular Automata Games

Damla Zerya Aslan

July 14, 2024

# Introduction

- ▶ Cellular Automata games are models where players interact with a grid of cells that evolve over time.
- ▶ In two-player Celata games players alternately change the state of cells.
- ▶ Error-correcting codes are constructs for detecting and correcting transmission errors.
- ▶ Linear error-correcting codes use algebraic methods for encoding and decoding.

# Preliminaries

- ▶ Games on a digraph  $G = (V, E)$  with  $V = \{z_1, \dots, z_n\}$ .
- ▶ Tokens distributed on vertices; moves involve selecting and moving tokens.
- ▶ Vertex labeling:  $N$  if the next player has a winning move,  $P$  otherwise.

$$F(u) = \{v \in V : (u, v) \in E\}$$

$$u \in P \iff F(u) \subseteq N$$

$$u \in N \iff F(u) \cap P = \emptyset$$

# Preliminaries

- ▶ The numerical value of a vector  $u = (u_0, \dots, u_{n-1}) \in GF(2)^n$  is:

$$|u| := \sum_{i=0}^{n-1} u_i 2^i$$

- ▶ The weight of  $u$  is the number of 1-bits in  $u$ :

$$w(u) = \sum_{i=0}^{n-1} u_i$$

- ▶ The Grundy number (or nimber)  $g(x)$  of a position  $x$  in a combinatorial game is defined recursively as:

$$g(u) = \text{mex}\{g(v) : v \in F(u)\}$$

## Example

- Consider the game graph below and compute Grundy numbers:

$$g(z_0) = 1$$

$$g(z_1) = 0$$

$$g(z_2) = 0$$

$$g(z_3) = 0$$

$$g(z_4) = 1$$

$$g(z_5) = 0$$

$$g(z_6) = 0$$

$$g(z_7) = 0$$

## Vector Matrix

- ▶ Construct the vector matrix  $W$  for the game:

$$W = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 \end{bmatrix}$$

- ▶ Each row corresponds to a vertex  $z_i$  in the game.

# Vector Space Operations

## Theorem

*In the vector space  $V$ , the sum of any two vertices  $u, v \in V$  is given by their vector addition in  $GF(2)$ .*

Proof.

$$u = \sum_{i=0}^{n-1} u_i z_i$$

$$v = \sum_{i=0}^{n-1} v_i z_i$$

$$u \oplus v = \sum_{i=0}^{n-1} (u_i \oplus v_i) z_i$$

# Vector Space Operations

- ▶ Summing vectors in  $GF(2)$ :

$$u = (1, 0, 0, 0, 1, 0, 0)$$

$$v = (0, 1, 0, 1, 0, 0, 0)$$

$$u \oplus v = (1, 1, 0, 1, 1, 0, 0)$$

- ▶ Hamming distance between vectors:

$$u = (1, 0, 0, 0, 1, 0, 0)$$

$$v = (0, 1, 0, 1, 0, 0, 0)$$

$$H(u, v) = w(u \oplus v) = w(1, 1, 0, 1, 1, 0, 0) = 4$$

# Lexicodes

## Definition

Lexicodes are a type of error-correcting code that can be generated using lexicographic order on binary vectors.

- ▶ Lexicodes are constructed by selecting vectors in lexicographic order with a minimum Hamming distance.

$$\text{Lexicode } L = \{v \in V_m : \text{Hamming distance } d \geq 5\}$$

$$g(z_j) = \text{mex}\{g(z_{i_1}) \oplus g(z_{i_2}) \oplus \dots \oplus g(z_{i_j})\}$$

# Lexicode Algorithm

- ▶ Calculate  $g(z_m)$  for each state  $m$ .
- ▶ Identify seeds (not sums of smaller  $g$ -values).
- ▶ Generate basis members from seeds.
- ▶ Apply greedy algorithm for lexicode.

$$\text{Lexicode } L = \{v \in V_m : \text{Hamming distance } d \geq 5\}$$

## Example

- ▶ Consider a game with  $n = 5$  and 3 dimensions.
- ▶ Basis vectors:

$$v_1 = (1, 0, 0, 0, 0), \quad v_2 = (0, 1, 0, 0, 0), \quad v_3 = (0, 0, 1, 0, 0)$$

- ▶ Linear independence means no vector in the set can be represented as a linear combination of the others.

$$a_1 v_1 + a_2 v_2 + a_3 v_3 = 0$$

$$a_1 = a_2 = a_3 = 0$$

## Greedy Algorithm for Lexicodes

- ▶ Start with the smallest vector not yet in the code.
- ▶ Add vectors in lexicographic order, ensuring a minimum Hamming distance.
- ▶ Example: Start with  $v_1 = (1, 0, 0, 0, 0)$ .
- ▶ Add  $v_2 = (0, 1, 0, 0, 0)$  if  $H(v_1, v_2) \geq d$ .  
Lexicode  $L = \{v \in GF(2)^5 : \text{Hamming distance } d \geq 2\}$

- ▶ Construct the vector matrix  $W$  for the game:

$$W = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 \end{pmatrix}$$

- ▶ Each row corresponds to a basis vector.
- ▶ Lexicodes:

$$\{(1, 0, 0, 0, 0), (0, 1, 0, 0, 0), (0, 0, 1, 0, 0), (0, 0, 0, 1, 0), \\ (0, 0, 0, 0, 1), (0, 1, 0, 0, 1), (0, 0, 1, 1, 0), (0, 0, 1, 0, 1)\}$$

# Forcing a Win

- ▶ Strategy based on  $g$ -function to determine  $P$ -,  $N$ -, and  $D$ -positions.
- ▶ Representations and follower functions.

$$Fe(u_e, u_j, v_j) = u_e \cup \{v_j\} \setminus \{u_j\}$$

$$Fe(u_e) = \bigcup_{j=1}^h \bigcup_{v_j \in F(u_j)} Fe(u_e, u_j, v_j)$$

# Lexicodes

- ▶ Apply equations for forcing a win to identify winning positions.
- ▶ Use these positions to derive lexicodes restricted to winning configurations.

$$Fe(u_e, u_j, v_j) = u_e \cup \{v_j\} \setminus \{u_j\}$$

$$Fe(u_e) = \bigcup_{j=1}^h \bigcup_{v_j \in F(u_j)} Fe(u_e, u_j, v_j)$$

$$\gamma(u_e, \xi(v_e)) = w_e \subseteq R_j, \quad \xi(w_e) \in F(\xi(v_e)) \cap V_p$$

- ▶ Construct lexicodes using only winning positions identified by  $Fe(u_e)$  and  $\gamma(u_e, \xi(v_e))$ .

Thank You for Listening!
